ABSTRACT

A method and apparatus for training a neural network to compute hazard functions for

customers and analyzing hazard functions, both for an individual customer, and for set of

5   customers to focus marketing techniques. The hazard function represents the likelihood of churn

for a particular customer. The gain in lifetime value is also calculated for each customer which

incorporates the present value of the customer with the future value of the customer if a new

contract is entered. The overall shape of the hazard function, combined with the gain in lifetime

value, specifies what marketing techniques are to be applied together with what additional

10   incentives are to be offered to the customer in order prevent churn.
